GitHub Link: https://github.com/DanSadeh/fNIRS-Signal-Processing

Goal: To extract relative concentration changes of oxygenated (ΔHbO) and deoxygenated (ΔHbR) hemoglobin from raw fNIRS intensity data, and to isolate the physiological heartbeat from system noise using frequency domain analysis.

Theoretical Background: Neural activity demands oxygen. By shining near-infrared light into the brain and measuring its attenuation, we track these hemodynamic changes. Because light scatters through biological tissue, we use the Modified Beer-Lambert Law (MBLL). The raw data collected by the machine is unitless light intensity. To convert this exponential light decay into a linear scale that we can solve algebraically, we take the base-10 logarithm (log_{10}). The final output gives us the physical concentration changes in microMolar (µM).

Equations:

Optical Density: $OD = log_{10}\left(\frac{I_0}{I_t}\right)$

Code: We calculate this using log10(intensityZeroL1 ./ intensityTimeL1).

Effective Pathlength: $L_{\{eff\}} = SDS \cdot DPF \cdot relDPF$

Code: We multiply the physical source-detector separation by the tissue-specific base DPF and the wavelength-dependent relative coefficient (leffL1 = sourceDetectorSep * baseDPF * relDPF1).

Concentration Change: $\Delta C = \varepsilon^{\{-1\}} \cdot \frac{OD}{L_{\{eff\}}}$

Question 2 - Time Domain Analysis:

dataFile1 = '.\FN_032_V1_Postdose1_Nback.mat';

dataFile2 = '.\FN_031_V2_Postdose2_Nback.mat';

Analysis: The MBLL successfully converted raw light intensity into concentration changes. By inverting the extinction coefficient matrix, the algorithm successfully "unmixed" the overlapping light absorption spectra of the two chromophores. The plots show ΔHbO and ΔHbR fluctuating inversely in the microMolar (μM) range over time. This makes physical sense, as an influx of fresh, oxygenated blood naturally displaces the oxygen-depleted blood during a standard hemodynamic response.

Question 3 - Frequency Domain Analysis & SNR:

```
Heartbeat Signal Strength: 1.0622e-08
Baseline Noise Level:      7.5488e-10
Heart rate (BPM):          57.6182
Final SNR:                 14.0717
```

Analysis: We transformed the time-domain signal into the frequency domain to isolate the cardiac cycle. We analyzed only the ΔHbO signal because the physical shockwave of the heartbeat is carried by fresh arterial blood; by the time blood becomes deoxygenated, the physical pulse is heavily damped. After normalizing the Fourier transform to preserve true physical amplitude, we mathematically removed the 0 Hz DC offset. We also plotted the graph starting at 0.2 Hz to intentionally hide massive, slow physiological artifacts (like respiration and Mayer blood-pressure waves) that would otherwise skew the visual scale. The algorithm successfully isolated a distinct cardiac peak at a resting heart rate of **57.6182 BPM**. With an SNR of **14.07**, the physiological heartbeat is proven to be vastly stronger than the high-frequency (> 2.5 Hz) hardware noise.

% Dan Sadeh 314631763
function [dHbR, dHbO, fig] = CalcNIRS(dataFile, sourceDetectorSep, tissueType, plotChannelIdx, ...
    extinctionCoefficientsFile, DPFperTissueFile, relDPFfile)

    % ----------------------------------------------------------------------
    % Description : The function calculates and plots HbR and HbO concentration
    %               changes using the Modified Beer-Lambert Law.
    % Assumptions : The data matrix 'd' contains exactly 40 columns (20 channels
    %               per wavelength). sourceDetectorSep is positive.
    % Inputs :
    %   dataFile - .mat file with intensity data (d), time (t), and Lambda.
    %   sourceDetectorSep - Source-Detector Separation distance in cm.
    %   tissueType - String matching a row in the DPF text file.
    %   plotChannelIdx - Vector indicating channels to plot.
    %   extinctionCoefficientsFile - .csv file with extinction parameters.
    %   DPFperTissueFile - .txt file with baseline DPF multipliers.
    %   relDPFfile - .csv file for wavelength-specific DPF adjustment.
    % Outputs :
    %   dHbR - HbR concentration change matrix (time x 20).
    %   dHbO - HbO concentration change matrix (time x 20).
    %   fig  - Handle to generated figures. Empty if no plots requested.
